This checklist is automatically generated using Version 3.0 of the online database CDF Galapagos Species Checklist.

This list of invertebrate species introduced to the Galapagos includes only species that did not arrive here by natural dispersal means like wind, water or with carrier animals. Instead these invertebrates were brought to the archipelago as a result of human activity, although mostly inadvertently so, introduced by accident, hidden in goods like produce (vegetables and fruit), or among stock animals, and hidden in packaging or building material.

Only very few invertebrates were actually introduced on purpose. An example is the recent introduction of the Giant African Snail (*Achatina fulica*), a species brought to Galapagos in the erroneous belief that it could be commercialized as an ingredient of beauty creams. This checklist of introduced invertebrates is based on an inventory in the inhabited areas of the islands of Santa Cruz, San Cristóbal, Isabela and Floreana. The list includes a taxonomically rather heterogeneous group of species, such as insects, spiders, mollusks, crustaceans and any other organisms which do not have a spinal column. Among the worst invertebrate invaders of Galapagos are species like *Wasmannia auropunctata* (little red fire ant), *Solenopsis geminata* (tropical fire ant), *Brachygastra lecheguana* (black paper wasp), *Polistes versicolor* (paper wasp), and *Philornis downsi* (a fly living parasitic in the nostrils of birds, in Galapagos especially parasitizing chicks of Darwin finches).

Once they have arrived in Galapagos, introduced invertebrates are extremely difficult to control and they are almost always impossible to eradicate. Increasingly scientists therefore advocate the use of parasites or predators as biological control agents. These studies have to be extremely careful. Precautions are necessary to avoid any risk that an introduced parasite or predator may inadvertently affect not only its main target, but also become detrimental to the native species. It often takes years of careful studies to be certain that these risks can be minimized. Until this day biological control has therefore only once been carried out in Galapagos:

In 2002 scientists introduced *Rodolia cardinalis*, the cardinal ladybug, as a biological control of *Icerya purchasi*, the cottony cushion scale. This experiment has been extremely successful, as today population levels of *Icerya purchasi* have dropped drastically and the predator *Rodolia cardinalis* exclusively feeds on this plant parasite and does not affect any other native species.

For marine species distribution data cited in the CDF Galapagos Checklists refer to the five main bioregions of the archipelago (Far Northern, Northern, Western, South Eastern and the Elithabeth Bay Bioregion). For the terrestrial species the more than 120 islands, islets and small rocks have been aggregated into Islands Groups, thus, for example, the island group "Santa Cruz" includes smaller islands like Santa Fé, Plaza Norte, Plaza Sur, Baltra, Daphne Mayor, Daphne Minor, and others.

Please be aware that the distribution data presented here is automatically generated from specimen records and does not always accurately reflect the known distribution for all species.

IUCN red-list assessments presented here may deviate from the global IUCN list for the following reasons:

- for well known species groups like vascular plants or vertebrates updates proposed to the IUCN are shown instead of the outdated, but currently accepted status;
- for poorly known species groups (e.g., lichenized fungi) a general assessment is currently not possible and the list presented here is a regional red-list list for Galapagos archipelago.

Taxon status: Accepted name; taxon occurs in Galapagos.

Syn.: *Incisitermes galapagoensis*, *I. immigrans*. Light (1935) states that this species should be considered as a senior synonym of *I. tabogae* Snyder, 1924, but Nickle Collins 1992 use *I. tabogae* as a valid species. *I. galapagoensis* is a supposed endemic species from Islas Wolf and Genovesa. This species cannot be recognized by the descriptions. Cotypes are in the USNM, but Constantino (1998) states that the holotype adult was in CASC, and was destroyed. The distribution of *I. immigrans* is supposed to be Central Pacific Islands, (Hawaii, Marquesas, Fanning, Jarvis), El Salvador, Panama, and Peru; and widespread in the Galápagos. Light (1935) gives characters of soldiers to separate *I. immigrans* from *I. tabogae* (= *I. pacificus*), but I find both species" of soldiers in the same colony. I have listed above all island records of *Incisitermes* as *I. pacificus*
