This checklist is automatically generated using Version 3.0 of the online database CDF Galapagos Species Checklist.

The main characteristic of the **crustaceans** is the presence of a chitinous exoskeleton, periodically shed and replaced when the animal grows.

They have a segmented body, each segment with appendages. The functional variability of these appendages in different groups is a principal reason why these animals display an enormous evolutionary diversity. The appendages evolved into feet, antennae, gills, mandibles, etc. Sexual reproduction of crustaceans takes place when the female releases the eggs immediately after fertilization and the larvae either develop directly into forms that are morphologically identical to the adults, or pass through different larval stages that are morphologically very different from their fully-developed adult state.

For marine species distribution data cited in the CDF Galapagos Checklists refer to the five main bioregions of the archipelago (Far Northern, Northern, Western, South Eastern and the Elithabeth Bay Bioregion). For the terrestrial species the more than 120 islands, islets and small rocks have been aggregated into Islands Groups, thus, for example, the island group "Santa Cruz" includes smaller islands like Santa Fé, Plaza Norte, Plaza Sur, Baltra, Daphne Mayor, Daphne Minor, and others.

Please be aware that the distribution data presented here is automatically generated from specimen records and does not always accurately reflect the known distribution for all species.

IUCN red-list assessments presented here may deviate from the global IUCN list for the following reasons:

- for well known species groups like vascular plants or vertebrates updates proposed to the IUCN are shown instead of the outdated, but currently accepted status;
- for poorly known species groups (e.g., lichenized fungi) a general assessment is currently not possible and the list presented here is a regional red-list list for Galapagos archipelago.

Names of taxa included in this checklist: 238 (216 Accepted , 20 Unidentified Taxon , 2 Doubtful).

Origin of the taxa included: 22 Endemic, 9 Indigenous.
