

# CDF Checklist of Galapagos Flies

Bradley J. Sinclair

**Last updated:** 11 Feb 2014

## Abstract

This Checklist of Galapagos Flies includes a total of all 304 taxa reported from the Galapagos Islands.

For each name, detailed information is provided: its Galapagos distribution in islands groups or bioregions generated from the specimen records, comments about the taxonomy (especially synonyms), the origin (native and introduced), taxon status (accepted vs. rejected records) and relevant literature references.

## Introduction

This publication lists all species of Galapagos Flies currently known.

The **Diptera** are flies with only a single pair of wings, the second pair being reduced to halteres (knobs on short stems). True flies can thus be distinguished from other flying insects, such as mayflies, dragonflies, damselflies, etc. Some true flies, however, have become secondarily wingless.

The Diptera are one of the largest insect orders, containing an estimated 240,000 species worldwide. They are also of significant ecological, medical, and economic importance.

As in most island faunas, the Diptera of the Galapagos are unbalanced or disharmonic compared to the mainland fauna.

The diversity and ecology of the Diptera in the Neotropical source area determines which of them can and cannot arrive and survive in Galapagos. For example, the absence or poor representation of many aquatic groups is because most of the islands lack permanent fresh water.

## Methods

This checklist of all known Galapagos Flies is automatically generated using the online database of the Charles Darwin Foundation Galapagos Species Checklist.

All CDF Galapagos Species Checklists represent the synthesis of many different records: literature citations, data from previously unpublished reports (grey literature), specimen records of natural history collections located in Galapagos and all over the world. To the best of their knowledge authors of the individual checklists revised all available data. When new information becomes available, the taxonomy of a group changes or new species are discovered, the CDF online database and thus this publication becomes updated.

For many poorly known species groups the higher taxonomic classification still regularly changes according to how our knowledge about species being related changes. In many well known groups the phylogeny is somewhat stable, but to avoid confusion, in particular for groups where taxonomic changes are frequent, all checklists presented here are sorted alphabetical according to genus

name and specific epithet. Please refer to the website for the currently accepted taxonomic hierarchy of each group.

Please be aware that the distribution presented here is automatically generated from specimen records and does not always accurately reflect the known distribution for all species.

For marine species, the distribution generally refers to the five main bioregions of the archipelago (Far Northern, Northern, Western, South Eastern and the Elisabeth Bay Bioregion). For the terrestrial species more than 120 islands, islets and small rocks have been aggregated into Islands Groups, thus, for example, the island group "Santa Cruz" includes smaller islands like Santa Fé, Plaza Norte, Plaza Sur, Baltra, Daphne Mayor, Daphne Minor, and others.

IUCN red-list assessments presented here may deviate from the global IUCN list for the following reasons:

- for well known species groups like vascular plants or vertebrates updates proposed to the IUCN are shown instead of the outdated, but currently accepted status;
- for poorly known species groups (e.g., lichenized fungi) a general assessment is currently not possible and the list presented here is a regional red-list list for Galapagos archipelago.

Numbers of the species included in this list are auto-generated. Adding up the number of species in each category will not always equal the total number indicated. Some species have insufficient data to be categorized while others (e.g., category eradicated) will not be included in the total.

171. *Lucilia aff. pionia*

**Taxon status:** Taxon not identified to species, subspecies, form or variety.

Tantawi & Sinclair (2013): CNC specimens of *Lucilia*, other than *L. deceptor*, collected from the island of Española in 1985 are morphologically different from *L. pionia* specimens collected from other islands. Additionally, four males in CAS from Española that were originally identified as *L. setosa* by James share the same features. (...) Given this finding and due to the poor condition and low number of *L. pionia* males and few females of the above mentioned CNC specimens from Española, we prefer at present to treat the Española specimens as *Lucilia sp. near pionia*. The status of this apparent variant of *L. pionia* should be reevaluated when better specimens from Española become available.
